1. Introduction

The Lippeverband (LV) has commissioned the investigation of three wet chemical recovery processes within the framework of Phos4You to produce phosphoric acid.

- REMONDIS TetraPhos®
- Phos4Life™
- PARFORCE

The procedures are all based on the same principle (Figure 1). First, the phosphates are dissolved from the ash matrix using acid and the ash residue is separated. Since many undesirable accompanying or impurities (including iron, aluminum and calcium as well as heavy metals) are also transferred to the solution (raw phosphoric acid), the next step is the separation of impurities. Finally, the purified phosphoric acid is brought to the usual market concentration by evaporation.

2. P-recovery

The Lippeverband (LV) has commissioned the investigation of three wet chemical recovery processes within the framework of Phos4You to produce phosphoric acid.

- REMONDIS TetraPhos®
- Phos4Life™
- PARFORCE

The investigations carried out only provide a snapshot, since the composition of the SSAs used will change (seasonally) during the ongoing process. The resilience of the processes/procedures in continuous operation will only become apparent when they are implemented industrially over a longer period of time.

Particularly with regard to the quality and possible uses of the by-products and residual materials, there are still some uncertainties. Open questions about disposal routes or stable sales markets or recycling possibilities exist, but still need to be validated.

In the context of advancing technological implementation, the following points will play an essential role in the efficient design of phosphorus recovery from SSAs by wet-chemical processes:

- Process optimization/adaptations also in terms of operating chemical (including mineral acid - eluate) and energy requirement
- Process design in terms of by-product generation and quality

3. P-rich product

The quality and purity of the phosphoric acid produced is quite variable, depending on the effectiveness of the purification processes applied, and carries small amounts of accompanying substances (Table 1) in accordance with the starting substance (SSA). However, it can be stated that the phosphoric acids produced in the "Phos4You" project are of marketable quality.

4. Discussion

The procedures are all based on the same principle (Figure 1). First, the phosphates are dissolved from the ash matrix using acid and the ash residue is separated. Since many undesirable accompanying or impurities (including iron, aluminum and calcium as well as heavy metals) are also transferred to the solution (raw phosphoric acid), the next step is the separation of impurities. Finally, the purified phosphoric acid is brought to the usual market concentration by evaporation.

The quality and purity of the phosphoric acid produced is quite variable, depending on the effectiveness of the purification processes applied, and carries small amounts of accompanying substances (Table 1) in accordance with the starting substance (SSA). However, it can be stated that the phosphoric acids produced in the "Phos4You" project are of marketable quality.

5. Conclusion

In can be stated that the technological solution of wet-chemical phosphorus recovery from SSAs is generally applicable and that the legal requirements, such as those of the German Sewage Sludge Ordinance (target: recovery rate > 80%), can be met.

Further technological implementation will demonstrate feasibility and answer any remaining questions. The processes considered in Phos4You will be implemented on an industrial scale in further projects (Figure 3).
